Lentil

Lentil production is expected to increase in 2019 due to higher yields; however, quality is expected to fall because of unusual weather patterns affecting this year's crop. Quality may not have suffered as much as other crop types because lentil is usually harvested sooner and can often miss weather-related problems.

The growing season started off with a dry spell, followed by heavier amounts of precipitation later in the season—the reverse of expected weather conditions during the growing season. This caused more variability in yield throughout the province; however, the overall outcome will likely lead to increased production.

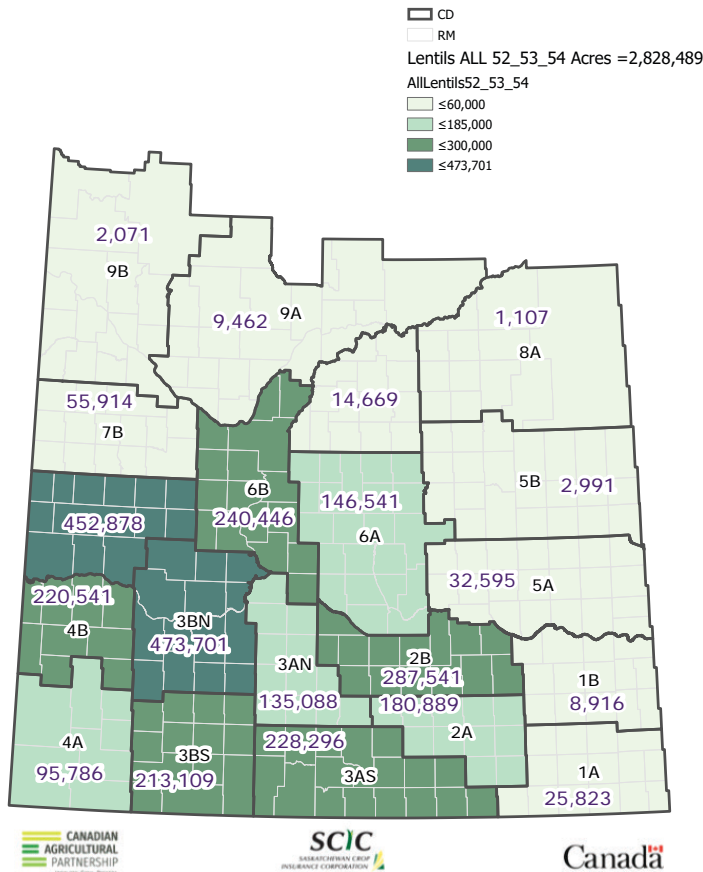

Much of the lentil production for 2019 is reportedly moving to India (despite tariffs), United Arab Emirates (UAE), Bangladesh and Turkey; however, this early-season demand from these export regions is anticipated to be the result of reports of lower quality. Lentil production in the United States is expected to drop due to fewer seeded acres, especially in Montana.

Dry Pea

The production of dry pea in 2019 is anticipated to be higher by about 30 per cent, mostly because of an increase in seeded area in Saskatchewan and Alberta. The yield for this production year is expected to be higher, as well.

Environmental impact on growth was variable for this year and it is likely that yields will vary accordingly. Initially Saskatchewan suffered through a very dry spring and many of the seeded peas did not germinate. When rain did come, it was later in the year and too much precipitation became an issue. Some of the problems suffered in previous years began to show again, such as aphanomyces and fusarium root rot. Overall, the pea crop seemed to cope quite well with the varying conditions and reached maturity without too many problems. Insects, such as aphids, were a problem in some spots, but not widespread.

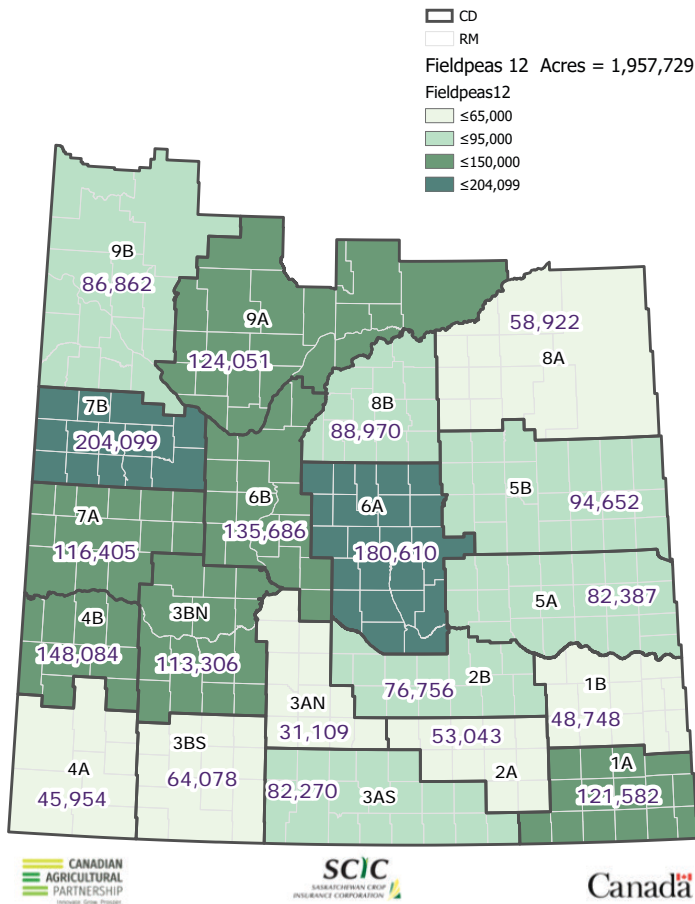

The largest export destinations are China, the United States and Bangladesh. Additionally, pea protein has become a major ingredient in many different food applications, such as Ripple, which is a plant-based milk made from yellow pea. The demand for yellow peas is expected to rise significantly in the coming years.

Chickpea

The 2019 production of chickpea is expected to drop because of fewer seeded acres and lower yields. Chickpea is an indeterminate crop and requires more days to reach maturity than other pulses grown in Saskatchewan. Much of the latter-season rains led to increased vegetative growth and less energy directed toward production.

The United States and Pakistan are Canada's largest export markets; however, exports were down largely due to increased chickpea production (2018-19) in the northern States (Montana and North Dakota). Therefore, Canada still has a large quantity of last year's crop in the bin. Production of chickpea worldwide is expected to increase in 2019-20 and Canadian chickpea quality is expected to fall, putting downward pressure on prices and Canadian exports.

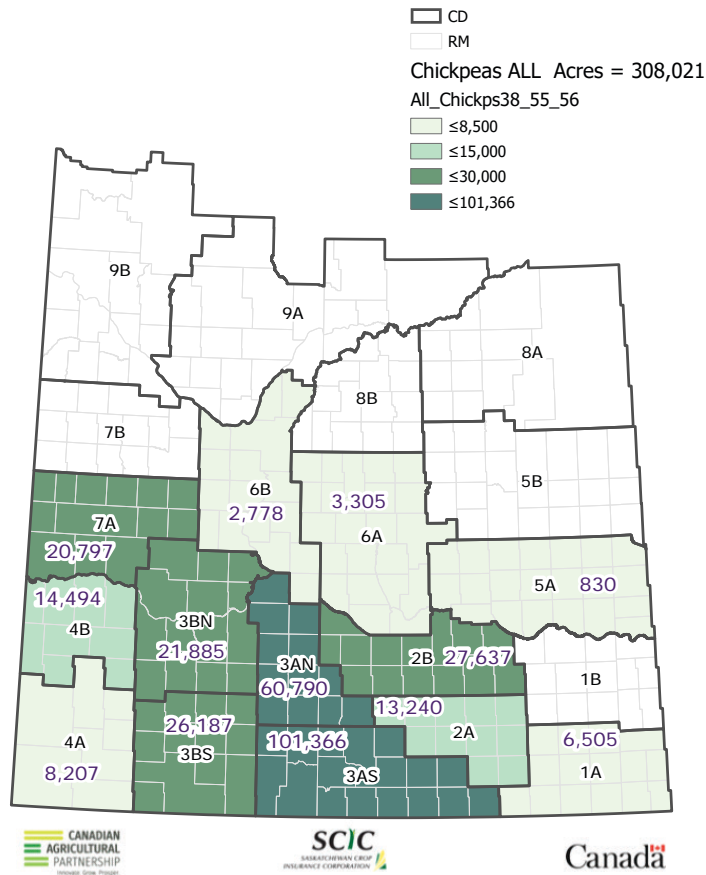

Saskatchewan is the largest Canadian producer of chickpea, which has been dominantly kabuli types; however, desi-type chickpeas have made a resurgence into the province, which, hopefully, may help to find new market opportunities.

Mustard

Three major types of mustard are grown in Saskatchewan: yellow, oriental and brown. Saskatchewan is a major producer of mustard and the product is highly renowned worldwide. In 2018-19, mustard carry-over quantities increased to 73,000 tonnes, causing concern of a buildup in supply. This may have sparked a decrease in seeded acres for 2019-20; however, yield was higher at 0.90 tonnes per hectare. Prices for mustard are forecast to increase in 2020-21.

Mustard crops were harvested late in 2019-20, which would have put them in to the period where Saskatchewan realized heavier rainfall. Historically, this type of weather usually adversely affected the crop, knocking down quality to #2 Canada for much of the production. This could mean that Canada may have less # 1 Canada, high-grade mustard to export in 2019-20. If the weather did not affect the quality, Canadian exports would benefit from the scenario. Additionally, it's important to know the proportion of mustard that was reduced the most. If brown and oriental make up most of the carry out, then yellow would be in tight supply and stand to benefit the most in 2020-21.

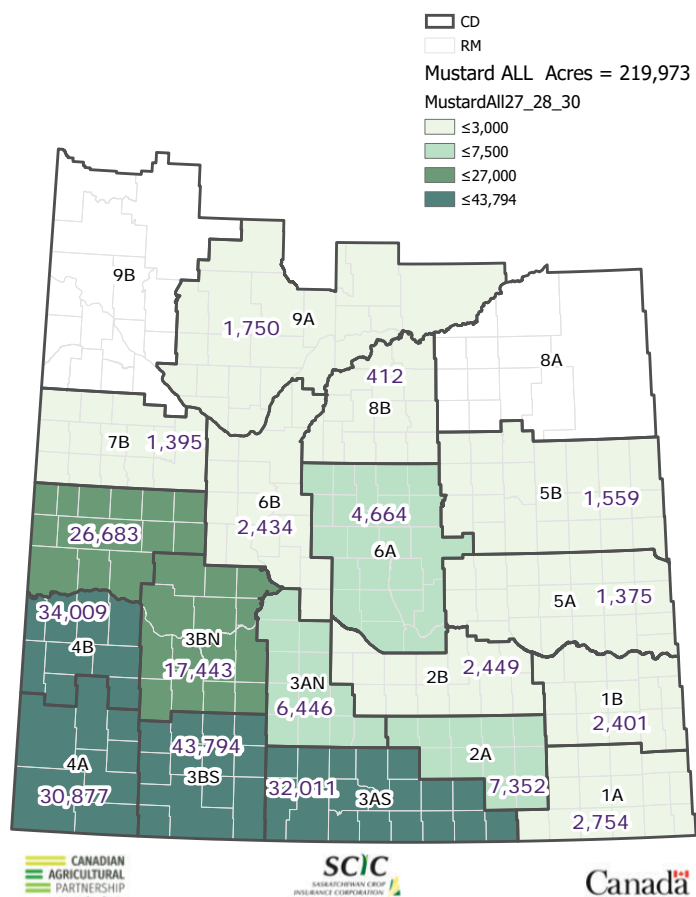

Mustard growers are excited about the new hybrid mustard with significantly increased yield potential, as well as new developments using mustard for livestock in various other functions.

Canaryseed

A combination of dry conditions and cool weather resulted in a slower start to the year and relatively late-maturing crop. Harvest conditions were further challenged with frequent rain and occasional snow. The final Crop Report survey estimated three per cent of the canaryseed remained in the fields.

Canaryseed grows well on heavier soils that are able to hold more moisture, but canaryseed is quite sensitive to dry conditions.

Yields were down from 2018, but only slightly below the five-year average provincially. Yields varied considerably by region. Regular canaryseed made up more than 73 per cent of harvested acres, but yielded only six per cent more than the hairless canaryseed. New varieties of hairless canaryseed are approaching the yield potential of the regular canaryseed. The hairless type, when dehulled, is now approved for human consumption in Canada and the United States.

Seeded area was nearly five per cent lower in 2019 than in 2018, at 236,800 acres; overall production is estimated to be 118,800 tonnes. Saskatchewan produces nearly 100 per cent of all canaryseed in Canada.

Exports in 2019-20 are expected to be slightly lower than 2018-19. Mexico, Brazil and Belgium were the top export markets for canaryseed, with strong markets in the United States and South American countries.

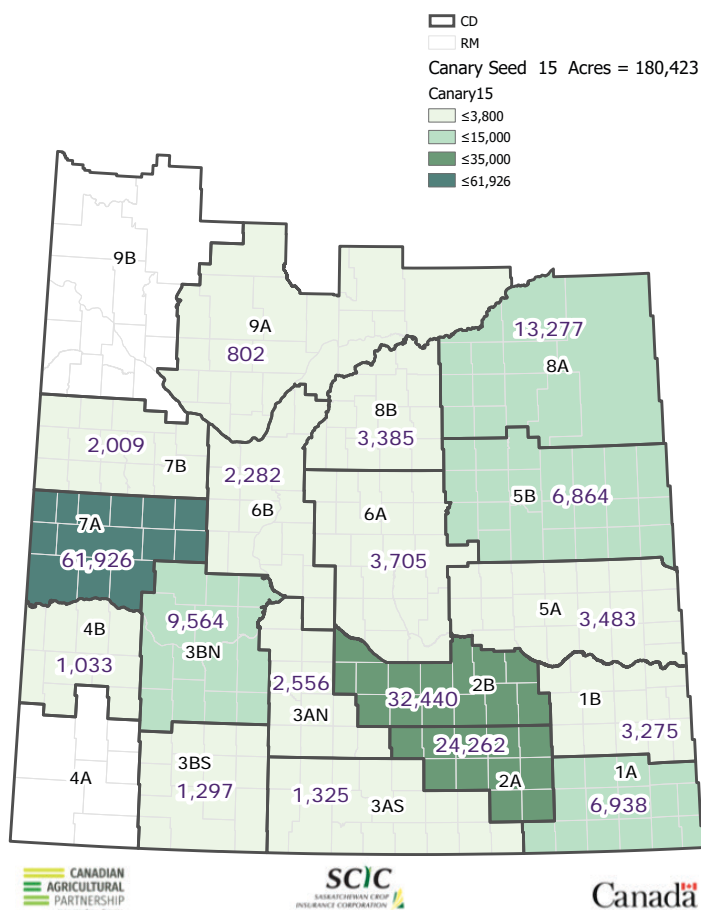

Carry-out stocks have been estimated as low for several years, which is normally an indicator that prices may increase. Fall 2019 prices were stronger than in recent years.

Soybean

Saskatchewan producers continue to consider adding soybeans to their crop rotation; however, seeded area has fallen over the past two growing seasons, causing drops in production. Much of the soybean acres are on the east side of the province, but some are grown more centrally and extend to the northwest area of the province. Soybean loves water and heat, and the critical timing for moisture is usually in late July and early August. Because of this requirement, soybean is a later-maturing crop and is often at risk for fall frosts.

Saskatchewan received a great deal of precipitation in latter parts of the growing season, which would have benefitted soybeans; however, they got off to a shaky start, as did most crops grown in the province this year, because of dry conditions. Expectations for soybean is a slight drop in yield and quality. Western Canadian soybeans have been plagued with lower protein levels compared to soybeans grown in eastern jurisdictions.

Overall, Canadian soybean production is also expected to drop for 2019 due to a drop in seeded area. Similar expectations are forecast in the United States; however, other parts of the world, such as Brazil, China, and India, are forecast to increase soybean production. This will widen the range for soybean pricing in 2020-21, and quality will likely be a major deciding factor.

Fall Rye

Fall 2018 through spring 2019 were stressful for overwintering crops. The winter was long and very cold, and the dry spring led to challenging conditions for winter cereals that would normally advance through reproductive stages before spring rains were received in 2019. Despite this, fall rye yields were quite good.

Fall rye is a winter cereal that can make use of moisture from winter and early spring precipitation. During spring thaw, the crop begins to actively grow and build yield potential. Fall rye is protected from dry conditions in late July and August due to earlier maturity than spring-seeded crops; however, limited crop development in the fall can delay harvest the following year.

Rye is an efficient scavenger and will perform better than other crops when nutrients and water are scarce, and also responds well to management. The introduction of hybrid rye led to the need for increased management. The hybrids considerably out-perform open-pollinated varieties.

Yields were 20 per cent above the five-year provincial average. Fall rye production averaged 47 bu/ac, nearing 2016 and 2017 records of 50 bu/ac, and is the third-highest yield on record.

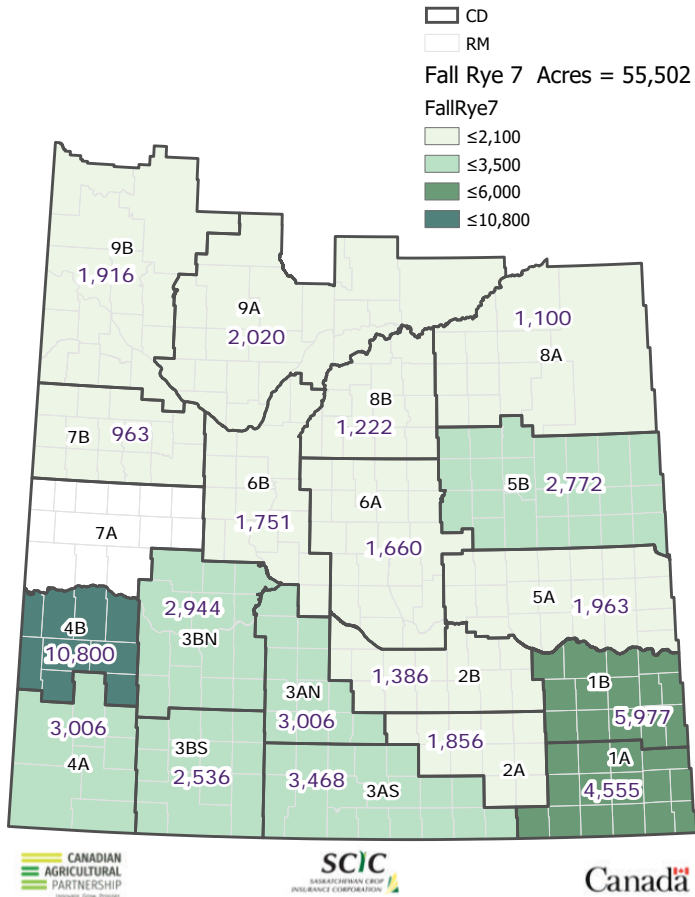

Seeded area was 10 per cent greater in 2019 than the five-year average, with 102,000 acres planted. There appears to be renewed interest in rye production. Overall production from the 2019 harvest is estimated to be 47,100 tonnes.

The United States is the top export market for fall rye, purchasing almost all Canadian exports.

Faba Bean

Interest in faba bean has increased in Saskatchewan for 2019-20. Much of the seeded area is found in wetter regions of the province, where faba bean thrives best. Some of the seeded area is also found in irrigated areas around the Outlook region.

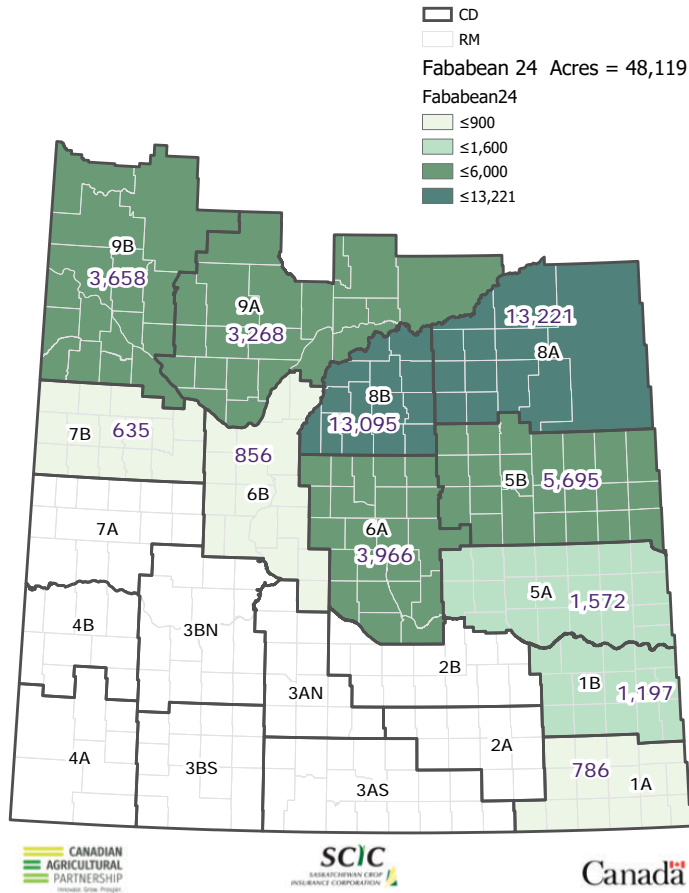

The market for faba bean is largely in Egypt; however, it is slowly expanding into Middle East North African (MENA) regions. There are two main types of faba bean grown in western Canada, segregated as to whether they contain high or low tannins. High-tannin types are typically preferred for food while the low-tannin types are often slated for feed for livestock. Much of the faba bean grown in Saskatchewan is the low-tannin type and is usually used for livestock. Recent development seemingly indicates that low-tannin types may become of interest for human consumption, as well.

New varieties with lower vicine/convicine (v/cv) levels have now been released, and it is expected faba bean may begin to usurp greater proportions of the plant protein market. Faba bean protein levels are typically over 30 per cent, which are higher than protein levels found in other common pulses. A major constraint is the production of older varieties versus availability of newly developed v/cv releases.
